Formulation

The mathematical formulation for our model pertaining to the *Pacific Paradise Gas* client is listed below. We identify the relevant data to the optimisation problem, and the stages/states/actions that provide the optimal solution to the profit maximisation problem. For the sake of this problem, we seek the optimal solution given by the value function $V_0(0,0,0)$ as defined below.

Data

```
d_t
        demand for no. of gas cylinders on day t
        high demand for no. of gas cylinders on day t
  hd_t
        demand for no. of large gas cylinders on day t
 LD_t
        probability of high demand of gas cylinders on any given day
    p
   r_n
        sale price (revenue) of a normal 45kg gas cylinder
        sale price (revenue) of a large 90kg gas cylinder
   r_L
        capacity for overnight 45kg cylinder storage
 cap_n
        capacity for overnight 90kg cylinder storage
cap_L
        base delivery cost
BDC
NDC
        normal (45kg) cylinder delivery cost
LDC
        large (90kg) cylinder delivery cost
Dcap
        maximum weight of cylinders available for transport on delivery truck
```

Stages

 M_n

 M_L

Days
$$t \in \{0, ..., 13\}$$

States

```
s_t number of stored 45kg cylinders on day t

L_t number of stored 90kg cylinders on day t
```

mass of a normal cylinder (45kg) mass of a large cylinder (90kg)

Actions

```
n_t number of 45kg cylinders to order/deliver on day t number of 90kg cylinders to order/deliver on day t
```

Value Function

$$V_{t}(t, s_{t}, L_{t}) = \text{expected maximum profit if we start day } t \text{ with } s_{t} \text{ 45kg and } L_{t} \text{ 90kg cylinders currently in storage}$$

$$= \max_{\substack{0 \leq n_{t} \leq \max_{n_{t}} \\ 0 \leq N_{t} \leq \max_{N_{t}}}} \{ \text{profit}(t, s_{t}, L_{t}, n_{t}, N_{t}) + pV_{t+1} (t+1, \text{ high_step}(t, s_{t}, L_{t}, n_{t}, N_{t}), \text{ large_step}(t, L_{t}, N_{t})) + (1-p)V_{t+1} (t+1, \text{ small_step}(t, s_{t}, L_{t}, n_{t}, N_{t}), \text{ large_step}(t, L_{t}, N_{t})) \}$$

Base Case

$$V_{14}(14, s_t, L_t) = 0$$

Supplementary Functions

```
\min \left\{ \operatorname{cap}_n - s_t + h d_t + 2 \times \operatorname{deficit}(t, L_t, N_t), \operatorname{floor}((\operatorname{Dcap} - M_L \times N_t) / M_n) \right\}
                                                             \max_{n_t}
                                                                                         \min \left\{ \operatorname{cap}_L - L_t + LD_t, \operatorname{floor}(\operatorname{Dcap}/M_L) \right\}
                                                            \max_{N_t}
                                deficit(t, L_t, N_t)
                                                                                         deficit function for how many large cylinders we're missing to meet (mandatory) demand
                                                                                         \operatorname{deficit}(t, L_t, N_t) = \max\{0, LD_t - L_t - N_t\}
                                           DC(n_t, N_t)
                                                                                         delivery cost function for delivering n_t 45kg and N_t 90kg cylinders:
                                                                                         DC(n_t, N_t) = BDC + NDC \times n_t + LDC \times N_t
            \operatorname{profit}(t, s_t, L_t, n_t, N_T)
                                                                                         profit for day t given the current storage (s_t, L_t) and the delivery (n_t, N_t)
                                                                                         \operatorname{profit}(t, s_t, L_t, n_t, N_t) = (p \times \min\{hd_t, s_t + n_t - 2 \times \operatorname{deficit}(t, L_t, N_t)\} +
                                                                                                                                                                             +(1-p)\min\{d_t, s_t+n_t-2\times \operatorname{deficit}(t, L_t, N_t)\})\times r_n+
                                                                                                                                                                             +LD_t \times r_L - \min\{n_t + N_t, 1\} \times DC(n_t, N_t)

                                                                                         large\_step(t, L_t, N_t) = L_t + N_t + deficit(t, L_t, N_t) - LD_t
```

Python Implementation

The model, programmed utilising a recursive value function, is available in the file attached with this document. Each (outdated) value function is given in this file, albeit without using many of the supplementary functions listed above.
